

# Direction Gesture: Side-Profile Pose Blocker

Now I understand the shape: it is not a front-palm or back-hand photo. It is a sideways/profile hand, like the fingers are stretched together as one thin arrow shape.

## Meaning

When the hand is held in this exact side-profile static pose, the app should not detect it as Moving left, Moving right, Moving up, or Moving down. The hand is only posing like an arrow; it is not a movement command.

Important: this does not mean all side-looking hands should be ignored. Only the very straight near-perfect profile pose should be blocked.

# The Four Poses To Block

Use the same side-profile hand shape for all four directions. Flip it for left or right, and rotate it for up or down.

## Block: Moving left

Exact side-profile hand pointing left

## Block: Moving right

Exact side-profile hand pointing right

## Block: Moving up

Same side-profile pose rotated upward

## Block: Moving down

Same side-profile pose rotated downward

# Code Logic I Understand

Keep the current direction detector. Add only one strict blocker after it already chooses a direction.

| Case                                             | What should happen                                 |
|--------------------------------------------------|----------------------------------------------------|
| Exact profile hand pointing left                 | Return none instead of Moving left.                |
| Exact profile hand pointing right                | Return none instead of Moving right.               |
| Exact profile hand pointing up                   | Return none instead of Moving up.                  |
| Exact profile hand pointing down                 | Return none instead of Moving down.                |
| Diagonal or imperfect pose                       | Do not block. Keep your existing direction result. |
| Majority direction with one finger different     | Do not block. Keep the existing majority logic.    |
| Zoom, recording, follow-object, package gestures | Do not change their priority or behavior.          |

## Strict Blocker Rule

After the detector chooses left, right, up, or down, check the extended finger chains. If every contributing chain points in the same selected direction and the cross-axis drift is tiny, return `HandMoveDirection.none`. A tolerance around 0.06 means the pose must be almost perfectly straight.

So the blocker is only for this exact side-profile arrow pose. It should not change normal movement, normal imperfect hand shapes, mirroring behavior, or higher-priority gestures.
